

Mapping Votes Against Land Area

One election, three thousand counties, and the difference between coloring land and counting people

Democracy's Data

Last updated 1 September 2026

San Bernardino County, California covers 51,976 square kilometers. It is larger than 9 of the 49 jurisdictions this brief maps, larger than Costa Rica, and on any map of the United States it is an unmissable slab of the desert southwest. In November 2024 it cast 740,530 votes for the two major presidential candidates. New York County, New York, the island of Manhattan, covers 58.7 square kilometers, 886 times less, and cast 647,703 votes.

Now recall the map you saw on election night: nearly the whole country red, with blue at the edges and in specks. It is probably the single most reproduced graphic in American politics, and it is the reason a great many Americans believe the 2024 election was a landslide. The two candidates finished 50.8 to 49.2 in the two-party vote, a gap of 1.6 points. So the question this brief asks is the one the map plants in every viewer: **when a county map is almost all one color, what exactly has been measured?**

01 The test

The map needs three things in the same rows: votes, boundaries, and land. The votes are county-level 2024 presidential returns from Tony McGovern's compilation (https://github.com/tonmcg/US_County_Level_Election_Results_08-24). **The federal government does not publish county-level presidential returns**, so every national county map rests on somebody's private reconciliation of fifty-one state publications, and this compiler's own README says the numbers are not authoritative. Why that is the ordinary condition of American election data is the returns-source chapter's subject. The boundaries and the land areas are federal: the Census Bureau's 2024 cartographic boundary file, whose `ALAND` field is the Bureau's own measurement in square meters, stored beside the outline rather than derived from it.

Counties are the right unit because they are the only one that works. States are too few and too internally mixed to show that color tracks acreage; precincts are not published nationally, and no federal file measures their land. Land, votes and boundaries meet at the county or nowhere. And because the county-returns brief has since assembled the same election from the fifty-one chief election offices, the compilation can now be measured against the certified record rather than merely doubted.

02 The data

The build joins the returns to the boundaries on the five-digit county FIPS code, read as **text, never as a number**. About a seventh of the codes begin with a zero, and a numeric read turns Autauga County, Alabama into a county in Georgia. Three places refuse the join, and each was settled by a documented decision:

Where the sources disagree	What goes wrong	What was done about it
Alaska	The returns report 40 State House Districts under invented FIPS codes; the geography file has 30 boroughs and census areas	Dropped whole (324,097 votes), along with Hawaii, which is outside the frame
District of Columbia	The returns report 8 wards, and 11001 means Ward 1, not the District	The 8 wards summed back to one District (325,869 votes)
Connecticut	The counties were abolished in 2022 and replaced by 9 planning regions	Nothing: the 2024 boundary file already reports the 9 regions, so the vintages agree

The District is the dangerous one, because it fails silently. 11001 is present in both files, meaning Ward 1 in the returns and the whole District in the geography, so the join succeeds and quietly discards 285,406 votes. The repair, summing the 8 wards back into one District, is one line. Knowing the line is needed is the whole job. Alaska cannot be repaired that way, so it is dropped whole, with Hawaii, which is outside the frame:

Why it is not on the map	Units	Votes involved
Alaska reports 40 State House Districts; the geography file has 30 boroughs	40	324,097
Hawaii lies outside the frame this map draws	4	516,701
summed into the District of Columbia, which is one unit in the geography	7	285,406

Every excluded unit is named individually, 51 rows carrying 1,126,204 votes, so the size of the hole sits on the page rather than in a footnote. What survives is 3,109 rows in `counties.csv`, one per county of the 48 contiguous states plus the District. Here is one:

Fips	Name	Dem	Rep	Total	Winner	Land km2
11001	District of Columbia	294,185	21,076	325,869	D	158.3

Each row carries the identifiers, the two vote columns and their total, the **winner**, the **margin**, the Bureau's `aland_km2`, and `density`, votes per square kilometer. A `pop` column from the Bureau's 2020 population file covers 3,100 of the 3,109 units, because that file predates Connecticut's 9 planning regions. Every headline number below is land, counties or votes, which exist for all of them. The outlines were thinned to 31.9% of their 208,983 corner points for drawing; every share quoted below was recomputed from the thinned outlines and moved by 0, because no headline number ever reads a boundary.

One more check, because the vote column is a press reconstruction. Put the mapped units against the certified assembly in the county-returns brief: 3,094 of 3,109 can be compared, and 47 disagree on a major-party count. One of those is a boundary dispute about Kansas City rather than an error. The ratio this brief turns on moves from 5.63 to 5.60 depending on which file you believe, which is to say it does not move. The doubt is measured now, not merely declared.

Before you read on, commit to a number. Trump carried 2,661 of the 3,109 counties on the map below – 85.6% of them, and 85.7% of the land. **What share of the votes on this map were cast inside those 2,661 counties?** Not what share Trump won: what share of all the two-party ballots on the map were cast anywhere inside a county he carried. Write down a percentage before you read on.

03 What it says about democracy

Figure 1. The 2024 presidential result, one color per county. A choropleth, a map that fills each area with a color, fits the question *who carried the ground you are standing on*, which is the question this figure answers and the only one. All 3,109 counties are filled with the color of the candidate who carried them, on an equal-area projection, so a square centimeter of paper is the same number of square kilometers everywhere on the page. Trump carried 2,661 counties, 85.6%, covering 85.7% of the land; Harris carried 448, covering 14.3%.

Every county in Figure 1 is the correct color. No boundary is wrong, no result is misreported, and no projection trick has been played. The mechanism is not subtle once it is stated. A map that fills areas with color encodes **area**, and the eye adds it up whether or not you asked it to. Area is a property of the ground, not of the people standing on it. Here is the same election as a ledger instead of a picture:

Quantity	Carried by Trump	Carried by Harris
Counties	2,661 (85.6%)	448 (14.4%)
Land area	6,560,363 km ² (85.7%)	1,095,132 km ² (14.3%)
Population, 2020	162,136,344 (49.8%)	163,518,331 (50.2%)
Votes cast for the two candidates	77,475,680 (51.1%)	73,995,056 (48.9%)

Read the second and third rows together. Trump's counties are 85.7% of the land and hold 49.8% of the people. The map is not misdrawn; **it is drawing the land row while the reader is reading the people row.** Put it as a rate: every vote Trump won sits on an average of 0.085 square kilometers of map, and every vote Harris won sits on 0.015. **A Trump vote is drawn 5.7 times larger than a Harris vote.** No chart anywhere may distort the size of its marks by 5.7 to 1 without saying so in the legend, and this one never says so.

The answer to the prompt above follows from where people live. Sorting the counties from emptiest to fullest and adding as you go:

Quantity	Value
Counties casting half the two-party vote (largest first)	161
Land those counties cover	6.6% of the total
Counties casting the other half	2,948
Land those counties cover	93.4% of the total
Median county, two-party votes	12,449
Median county, land area	1,581 km ²

The emptier half of the counties hold 66.1% of the country's land and 7.8% of its votes. 161 counties cast half of every ballot on this map, on 6.6% of its surface. So the answer is: 85.6% of the counties, 85.7% of the land — and **51.1% of the votes**. Most readers write down something in the seventies or eighties, and the gap between that guess and 51.1 is this brief's entire subject. The 448 blue counties are 48.9% of the electorate sitting on 14.3% of the ground.

Now draw the same table so that the ink tells the truth about votes. Each county becomes a circle whose **area is proportional to the votes cast there**; circles keep their positions as nearly as they can and are pushed apart until they stop overlapping. This is a Dorling cartogram — a cartogram is a map that sizes places by a quantity instead of by their ground. Not one vote has been added, removed or recounted.

Figure 2. The same 3,109 counties, with area proportional to votes. The radius is one constant times the square root of the county's two-party vote, so one square unit of circle is 149 votes anywhere on the page. The largest circle is Los Angeles County, California, at 3,606,971 votes. Red now covers 50.8% of the ink because Trump won 50.8% of the two-party vote. **You cannot look at this map and think the election was a landslide, because the ink is reporting the result rather than the terrain.**

Figure 2 is not a better map than Figure 1. It is a map of a different quantity, and the quantity happens to be the one an election is decided by. The price is real and measurable: the nudging moved the middle county 10.8 km from its true position and the furthest 370 km, and it stopped with 584 of 45,233 tested pairs still touching. Shape, adjacency and the ability to find your own county are gone. And the eye judges area badly, which is a century-old finding in graphical perception. Figure 2 is defensible only because the alternative is an encoding that is off by a factor of 5.7, not because area is a good channel.

Neither map is the repair for the other. A cartogram does not remove distortion; it chooses a different one. All the drawings are true, and none of them is *the* map. Which one gets published is a decision about what the reader will believe, and in most newsrooms it is made by whoever happens to own the template.

04 What this brief cannot tell you

It cannot tell you the choropleth is a lie. Figure 1 answers *who carried this ground*, and for county politics or the geography of a party's base that is exactly the right question. The failure is in reading it as an answer to *how did the country vote*, which is a different question with a different bottom number underneath it.

It cannot certify any particular county. The vote column is a press reconstruction; 47 of the 3,094 checkable counties disagree with the state canvasses on a major-party count. The aggregate survives, because a county would have to be wrong by the size of a city to move it. A sentence about one county should come from that state's certified return instead.

It cannot say counties are the right unit. They vary by a factor of 37,573 in electorate, they were drawn for administrative reasons, and the same election added up over different boundaries would give a different picture. That is the modifiable areal unit problem, the answer depending on how you cut the country up, and the areal-units brief takes it apart properly.

And it is not how the president is chosen. Electors are allocated by state, the level the electoral-map brief works at. The fill here is also binary, painting a 0.03-point county the same shade as a 93-point one. Alaska and Hawaii, 0.5% of the national ballots, are absent from every figure and every number, so this is a map of the contiguous states. And one election is one election: the concentration measured above is a fact about November 2024, not a law of American geography.

05 What you should have learned

- A county choropleth of the 2024 election is accurate in every county and still misleads, because it encodes land: Trump's counties cover 85.7% of the land and cast 51.1% of the votes.
- On Figure 1, one vote for the winner of empty counties gets about 5.7 times the ink of a vote for the winner of full ones — a distortion no legend admits to.
- The electorate is concentrated: 161 of 3,109 counties cast half the ballots, on 6.6% of the land.
- An honest encoding costs something else: sizing counties by votes reports the 50.8–49.2 result in the ink, and destroys shape, adjacency and findability to do it.
- There is no federal county-level presidential file; the map's votes are a volunteer compilation, and checking it against the certified state canvasses is what turns that doubt into a measured, small number.

06 Extensions

- `lorenz.csv` accumulates `cum_land` and `cum_votes` together, county by county. Find the point where half the land has been covered. What share of the votes is in it?
- `counties.csv` has `aland_km2`, `votes_tot` and `density`. Sort by `density` and compare the extremes. How many of the emptiest counties add up to one Manhattan?
- `excluded.csv` lists the units that could not be mapped, each with a `reason` and its `votes`. Add them up. How many real voters vanish from a map of the country?

- `parity.csv` compares, in difference, the headline numbers before and after the outlines were thinned. Nothing moved. Work out what a difference there would have meant.
- **Stretch.** The compilation carries every election back to 2008. Download 2020, rebuild the ledger, and see whether the land-versus-votes gap is growing.
- **Stretch.** Redraw Figure 1 with a diverging margin scale instead of the binary fill, and decide which of this brief's sentences would need rewriting.

07 Sources

Data

- County-level 2024 presidential returns: Tony McGovern, *US County Level Election Results 2008-2024*, https://github.com/tonmcg/US_County_Level_Election_Results_08-24, held in this book's `pres2024_counties.csv` (3,160 rows). Compiled from Fox News, Politico and New York Times reporting; **the compilation's own README states that the figures are not authoritative.** There is no federal publisher of county-level presidential returns. This is the file every figure in this brief is drawn from.
- Official county-level presidential returns, as published by the 51 state chief election offices: `pres2024_counties_official.csv` and its 2020 companion, 3,197 rows each, assembled by the county-returns brief with one row per jurisdiction recording the URL, the format, and whether the state calls the figures certified. Used here as a ruler and not as a source of paint: no figure is drawn from it.
- Associated Press, certified state-level presidential totals for 2024, held as `crosscheck_ap_2024.csv` (51 rows). Used only to score the two county files against a third that neither was built from.
- U.S. Census Bureau, 2024 cartographic boundary file, counties, 1:5,000,000: https://www2.census.gov/geo/tiger/GENZ2024/shp/cb_2024_us_county_5m.zip — retrieved 2026-08-11, 2,982,952 bytes, 3,235 features. Supplies both the outlines and the `ALAND` land areas.
- U.S. Census Bureau, 2020 centers of population by county: https://www2.census.gov/geo/docs/reference/cenpop2020/county/CenPop2020_Mean_CO.txt — retrieved 2026-08-11, 3,221 rows. Supplies the population column only.

The data itself

Every figure above is drawn from these tables. They are plain CSV, they open in a spreadsheet, and they are yours to take further.

`counties.csv`, `county_rings.csv`, `dorling.csv`, `excluded.csv`, `lorenz.csv`,
`parity.csv`, `state_rings.csv`

Method

- Dorling, D. (1996). *Area Cartograms: Their Use and Creation*. Concepts and Techniques in Modern Geography 59. University of East Anglia. — the circle cartogram of Figure 2.
- Monmonier, M. (1991). *How to Lie with Maps*. University of Chicago Press.
- Cleveland, W. S. and McGill, R. (1984). "Graphical Perception: Theory, Experimentation, and Application to the Development of Graphical Methods." *Journal of the American Statistical Association* 79(387): 531-554. — the finding that area is a poor channel, cited against Figure 2 above.

REBUILD THIS DATA YOURSELF, WITH AN AI ASSISTANT

I want to rebuild a public dataset from its original sources, without any starting files. Please do the following and show your work.

THE FIRST SOURCE. U.S. Census Bureau, cartographic boundary file for counties, 1:5,000,000 scale, 2024 vintage:

https://www2.census.gov/geo/tiger/GENZ2024/shp/cb_2024_us_county_5m.zip

A zip holding one shapefile; each feature is a county or county-equivalent, with its code, name, and land area. No account or key is needed.

THE SECOND SOURCE. The Bureau's 2020 county population centroids – the mean center of population for every county – a plain text file:

https://www2.census.gov/geo/docs/reference/cenpop2020/county/CenPop2020_Mean_CO.txt

THE THIRD SOURCE. County-level 2024 presidential returns from the tonmcg compilation on GitHub

([tonmcg/US_County_Level_Election_Results_08-24](#)), the 2024 CSV fetched raw from the master branch: one row per county with Democratic, Republican, and total votes.

WHAT TO BUILD.

1. A map frame: every county that can be drawn and joined to a return – code, name, state, votes, winner, land area, and density – dropping territories and units the returns file does not carry.
2. The land-against-people arithmetic that maps of this election encode: the share of counties and of land area carried by each party, next to the share of actual votes.

CHECK YOUR WORK. The copies this book used were fetched in August 2026. If your rebuild matches them, you should find:

- the boundary zip is 2,982,952 bytes and holds 3,235 features; after the drops, 3,109 counties are mapped and 126 features are set aside
- the returns file has 3,160 rows carrying 154,863,739 votes
- the centroid file has 3,221 rows
- the Republican candidate carries 2,661 of the 3,109 counties –

6,560,363 of 7,655,495 square kilometers of land – while winning about half the vote; that gap is the point

The Bureau reissues the boundary and centroid files by vintage, and the compilation can change without notice; a difference means a source moved, not that you made an error.
